The width-aware totalLite...

Entry 5ab75839b6f0 · INCONCLUSIVE

SEC autonomous research engine — attribution: Ludovico Kubler

2026-06-13 11:15:46 UTC

[c003b_cumulative_entropy/SC3#c14] The width-aware total-LiteralWeight $\sum_t \sum_{C \in \sigma_t} |C|$ scales with a strictly larger exponent than the count-based Φ (width amplifies cumulative weight).

Entry ID: 5ab75839b6f0 **Verdict:** INCONCLUSIVE **Recorded:** 2026-06-13 11:15:46 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

The width-aware totalLiteralWeight $\sum_t \sum_{C \in \sigma_t} |C|$ scales with a strictly larger exponent than the count-based Φ (width amplifies cumulative weight).

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(\pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d-regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n, separator size |S|, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 2449d1816eb342a5

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the ratio of width-aware totalLiteralWeight to count-based Φ exceeds a strictly larger exponent for at least 80% of the seeds, with an aggregate mean ratio ≤ 3 across all seeds.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	UNCERTAIN	1.00	UNCERTAIN	HITS
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=1.0s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per-n wallclock guard so a hard instance does not stall the cycle.

- Separate log-log slope fits for `phi_count` (SC1) and `phi_weight` (SC3).
- Path-graph control at `n=12` (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at `n=12` on `seed[0]` (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure `stdlib` (no `networkx/pysat`). Protocol: `run_trial(seed)->dict` with `TRIAL/RESULT` lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code focuses on the cumulative entropy and width-aware totalLiteralWeight for Tseitin formulas on random 3-regular graphs. However, it does not provide evidence that the conjecture holds for all possible graph structures or instances beyond the tested range of n (6 to 16). The small sample size and limited range of n may not be sufficient to confirm the conjecture's validity.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test results show that the conjecture holds for the tested range of n (6 to 16), but the critic challenges the validity of the conjecture due to the limited sample size and range. The pre-registered support condition is not unambiguously met. | next: Expand the range of n and increase the number of seeds to test the conjecture across a wider variety of graph structures.

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in research/audit/5ab75839b6f0.jsonl for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: research/pvsnp_sandbox/test_*.py (per-cycle)

Replay tarball: research/replay/5ab75839b6f0.tar.gz (if generated)
