Minimal Order of Symplectic Leaves Bounds Resolution Proof Width

Entry ID: 9d633f15ba5a **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-30 04:03:32 UTC

1. Conjecture

Field A (mathematical branch): Symplectic Geometry **Field B** (complexity object): Resolution proof complexity

Statement:

For a symplectic manifold X with minimal leaf decomposition, the width of the resolution proof for any CNF in P sat by X is upper bounded by the minimal order of leaves (number of leaves) in the decomposition.

Rationale (proposer's reasoning):

Symplectic geometry provides a geometric structure that could capture the complexity of Resolution proofs. The minimal order of leaves offers a quantifiable measure of this structure's complexity, which might correlate with the resolution proof width.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 6b6385888e880d97

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if for all generated CNFs in P sat by X , the mean resolution proof width is less than or equal to the minimal order of leaves in the decomposition.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
KARP_LIPTON	SAFE	0.50	UNCERTAIN	UNCERTAIN

4. Novelty audit

Verdict: NOVEL against 0 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - "symplectic geometry" AND "resolution proof complexity" AND minimal leaf decomposition" - "minimal order of symplectic leaves" AND bounds AND resolution proof width" - "CNF in P satisfied by a symplectic manifold" AND resolution proof AND width

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=0.4s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code provided does not implement the conjecture’s primitive of ‘minimal order of symplectic leaves’. It instead computes a metric called ‘phi_count_loglog_slope_vs_n’, which is related to resolution proof width but does not directly measure the number of leaves in the minimal leaf decomposition. The metric may be bounded by construction, making the bound trivial.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code does not implement the conjecture’s primitive of ‘minimal order of symplectic leaves’. Instead, it computes a related metric called ‘phi_count_loglog_slope_vs_n’, which may be bounded by construction and does not directly measure the number of leaves in the minimal leaf decomposition. | next: Implement the conjecture’s primitive correctly and retest to verify if the conjecture holds.

11. Audit log (LLM calls)

Total LLM calls: 6

#	Phase	Provider	Model	Tokens in	out	Latency (ms)
1	propose	ollama_remote	glm4:latest	0	0	19707
2	preregistration	ollama_remote	glm4:latest	0	0	13372

(full prompt+response transcripts available in `research/audit/9d633f15ba5a.jsonl`)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/9d633f15ba5a.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/9d633f15ba5a.tar.gz` (if generated)
