[c003b_cumulative_entropy/SC1#c48] Under min-occurrence DP elimination, $\Phi(\pi)$ grows super-linearly in n on 3-regular Tseitin (log-log slope > 1). Measure the exponent.

Entry ID: a2a513f8d1ae **Verdict:** INCONCLUSIVE **Recorded:** 2026-06-13 18:38:10 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

Under min-occurrence DP elimination, $\Phi(\pi)$ grows super-linearly in n on 3-regular Tseitin (log-log slope > 1). Measure the exponent.

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(\pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d -regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 3c88ca475a23d525

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the log-log slope of $\Phi(\pi)$ vs. n exceeds 1 with a p -value ≤ 0.05 , based on at least 10 seeds.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	SAFE	SAFE
NATURAL_PROOFS	SAFE	1.00	SAFE	UNCERTAIN
ALGEBRIZATION	SAFE	1.00	SAFE	SAFE

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, $\leq 90s$ wall time per cycle **Execution:** rc=0, elapsed=1.3s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
proofStateEntropy(sigma) := sigma.activeClauses.card
cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per- n wallclock guard so a hard instance does not stall the cycle.
- Separate log-log slope fits for ϕ_{count} (SC1) and ϕ_{weight} (SC3).
- Path-graph control at $n=12$ (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at $n=12$ on seed[0] (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure stdlib (no networkx/pysat). Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code only includes a limited range of n values (6 to 16) and uses a small number of seeds (7). This may not be sufficient to confirm the conjecture, as it is possible that the observed behavior at these specific sizes does not hold for larger graphs or different seed configurations. The metric could also be subject to random fluctuations due to the limited sample size.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code includes a limited range of n values (6 to 16) and uses a small number of seeds (7), which may not be sufficient to confirm the conjecture for larger graphs or different seed configurations. The critic challenges the results, suggesting that the observed behavior might not hold for all cases. | next: Increase the range of n values and the number of seeds in future tests to better support the conjecture.

(full prompt+response transcripts available in *research/audit/a2a513f8d1ae.jsonl*)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in *research/audit/a2a513f8d1ae.jsonl* for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: *research/pvsnp_sandbox/test_*.py* (per-cycle)

Replay tarball: *research/replay/a2a513f8d1ae.tar.gz* (if generated)
