Minimal Tropical Hodge Index Bounds Resolution Proof Width

Entry ID: 5e0978a94e5f **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-30 06:22:57 UTC

1. Conjecture

Field A (mathematical branch): Tropical Geometry × Algebraic Geometry **Field B** (complexity object): Resolution proof complexity

Statement:

For a given Tseitin formula φ with n variables, the minimal tropical Hodge index of its associated tropical variety $H(\varphi)$ is $O(\log(n))$ when considering tree-like resolution proofs. Formally, there exists a constant c such that for all φ , $H(\varphi) = \Theta(\log(n))$, where $H(\varphi)$ is the minimum over all tropical divisors D of $H(\varphi)$ of the sum of their intersection numbers with the generic hyperplane.

Rationale (proposer's reasoning):

The minimal tropical Hodge index captures the complexity of the tropical variety associated with a Boolean formula, which can be seen as a geometric counterpart to its resolution proof size. By linking this invariant to the resolution proof width, we might uncover a new way to understand the inherent structure of computational problems in complexity theory.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 911d3aa245a3101b

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the average of the minimal tropical Hodge indices across all seeds is within ± 1 standard deviation of $\Theta(\log(n))$ AND the correlation coefficient between the minimal tropical Hodge index and the resolution proof width is ≥ 0.7 .

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	SAFE	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	1.00	SAFE	SAFE
KARP_LIPTON	SAFE	1.00	UNCERTAIN	SAFE

4. Novelty audit

Verdict: NOVEL against 0 hits across arXiv + Semantic Scholar + ECCC

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=0.5s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code provided does not implement the tropical Hodge index calculation for Tseitin formulas. It computes a metric called 'phi_count_loglog_slope_vs_n', which is not related to the tropical Hodge index. The empirical test focuses on resolution proof width, which is different from the conjecture's requirement of minimal tropical Hodge index bounds.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code does not calculate the tropical Hodge index as required by the conjecture but instead computes a metric called 'phi_count_loglog_slope_vs_n'. The empirical test focuses on resolution proof width, which is different from the conjecture's requirement. Therefore, the support condition for the conjecture cannot be unambiguously met. | next: Implement the tropical Hodge index calculation as specified by the conjecture and retest.

11. Audit log (LLM calls)

Total LLM calls: 8

(full prompt+response transcripts available in `research/audit/5e0978a94e5f.jsonl`)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/5e0978a94e5f.jsonl` for verification of provenance

4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/5e0978a94e5f.tar.gz` (if generated)
