Minimal Order of Affine Plane Curve Intersection Bounds Resolution Proof Width

Entry ID: 7e47a7fc5f53 **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-30 04:55:22 UTC

1. Conjecture

Field A (mathematical branch): Affine Geometry **Field B** (complexity object): Boolean Function Complexity: Resolution Proof Complexity

Statement:

For a satisfiable 3-CNF formula φ with n variables, the minimal order of the affine plane curve defined by the intersection points of the level sets of the monomial terms in φ bounds the resolution proof width. Specifically, $O(n) \geq \omega(\varphi)$, where $\omega(\varphi)$ is the resolution proof width.

Rationale (proposer's reasoning):

Affine geometry has been historically applied to algebraic surfaces and curves. The minimal order of an affine plane curve intersection may encode geometric properties that are not apparent in the Boolean structure of a formula, potentially providing deeper insights into the complexity of resolution proofs.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 066f350f2ddf4aaf

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the Spearman rank correlation coefficient between the minimal order of the curve intersection and the resolution proof width for all generated formulas is ≥ 0.7 , where $n \leq 40$.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	UNCERTAIN	1.00	HITS	UNCERTAIN
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
KARP_LIPTON	SAFE	1.00	SAFE	UNCERTAIN

4. Novelty audit

Verdict: NOVEL against 0 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - "affine plane curve intersection" AND "resolution proof complexity" AND "Boolean function" - "minimal order of intersection bounds" AND "resolution proof width" AND "affine geometry" - "3-CNF formula" AND "level sets monomial terms" AND "proof width"

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=0.5s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code provided does not implement the conjecture’s primitive of ‘affine plane curve defined by the intersection points of the level sets of monomial terms’. Instead, it computes a metric related to resolution proof entropy, which is unrelated to the geometric interpretation of the conjecture. The empirical evidence is based on a small number of instances ($n \leq 15$), which may not be sufficient to confirm the conjecture.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code does not implement the conjecture’s primitive of ‘affine plane curve defined by the intersection points of the level sets of monomial terms’. Instead, it computes a metric related to resolution proof entropy. The critic challenged the validity of the evidence due to the small number of instances tested and the lack of a direct implementation of the conjecture. | next: Implement the conjecture’s primitive in the test code and conduct a larger-scale empirical study with $n \leq 40$ to val

11. Audit log (LLM calls)

Total LLM calls: 6

(full prompt+response transcripts available in <research/audit/7e47a7fc5f53.jsonl>)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/7e47a7fc5f53.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/7e47a7fc5f53.tar.gz` (if generated)
