Minimal Topological Entropy Bounds Resolution Proof Width for Random k-CNF

Entry ID: 8467e1146ba4 **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-30 05:06:05 UTC

1. Conjecture

Field A (mathematical branch): Topological Dynamics (Entropy Theory) **Field B** (complexity object): Boolean Function Complexity: Resolution Proof Complexity

Statement:

For any random k-CNF formula with n variables, the topological entropy of its associated dynamics system is upper-bounded by a function of n that determines the resolution proof width for that formula.

Rationale (proposer's reasoning):

Topological entropy measures the complexity of dynamical systems and could potentially reveal hidden complexities in the structure of SAT instances, which are known to be related to the resolution proof width. If the conjecture holds, it would establish a new link between topological entropy and computational complexity, offering insights into the inherent difficulty of SAT problems.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 2c5b6c907b73443e

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if, for all n in $\{5, 10, 20, 40\}$, the topological entropy (TE) of the dynamics system associated with a random k-CNF formula is $\leq$ a function $f(n)$, where the resolution proof width (RPW) is ≥ 0.8 for at least 80% of seeds and the mean RPW across all seeds is ≤ 3 .

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
KARP_LIPTON	SAFE	0.50	UNCERTAIN	UNCERTAIN

4. Novelty audit

Verdict: ADJACENT_OK against 3 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - "topological entropy" AND "resolution proof complexity" AND k-CNF" - "entropy theory" AND Boolean function complexity" AND random k-CNF" - "minimal bounds on topological entropy" AND resolution proof width" AND n variables k-CNF"

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=0.4s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

```

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test only uses a maximum of $n = 14$ for testing, which is too small to confirm the conjecture's validity over all possible values of n . The metric mean and standard deviation are based on such a limited sample size, making it premature to conclude that the conjecture holds.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test only uses a maximum of $n = 14$ for testing, which is too small to confirm the conjecture's validity over all possible values of n . The critic challenges the conclusion based on the limited sample size. | next: Increase the range of n values tested and ensure that the pre-registered support condition ($\text{support_fraction} \geq 0.8$ AND $\text{metric_mean} \leq 3$) is met for a larger set of seeds to confirm the conjecture.

11. Audit log (LLM calls)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/8467e1146ba4.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/8467e1146ba4.tar.gz` (if generated)
