[c003b_cumulative_entropy/SC2#c19] $\Phi(\Pi) \geq c \cdot |S|^2$ for a constant $c > 0$, where $|S|$ is the balanced separator size (the cumulative-entropy analogue of the space lower bound that A13 needs).

Entry ID: 59aa8bd8bca4 **Verdict:** INCONCLUSIVE **Recorded:** 2026-06-14 07:01:06 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

$\Phi(\Pi) \geq c \cdot |S|^2$ for a constant $c > 0$, where $|S|$ is the balanced separator size (the cumulative-entropy analogue of the space lower bound that A13 needs).

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(\Pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d -regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): c47f858221d9d37b

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the mean cumulative entropy $\Phi(\Pi)$ across all seeds is greater than or equal to $c \cdot |S|^2$, where $|S|$ is the balanced separator size and c is a constant greater than zero. The conjecture is falsified if any seed produces a cumulative entropy $\Phi(\Pi)$ less than $c \cdot |S|^2$.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤ 90 s wall time per cycle **Execution:** rc=0, elapsed=1.2s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
  Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
  proofStateEntropy(sigma) := sigma.activeClauses.card
  cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per-n wallclock guard so a hard instance does not stall the cycle.
- Separate log-log slope fits for phi_count (SC1) and phi_weight (SC3).
- Path-graph control at n=12 (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at n=12 on seed[0] (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure stdlib (no networkx/pysat). Protocol: `run_trial(seed)->dict` with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code focuses on the computation of cumulative proof entropy for resolution refutations of Tseitin formulas on random 3-regular graphs. However, it does not provide evidence that this metric directly corresponds to the conjecture’s definition of balanced separator size in terms of cumulative entropy. The test may be measuring something related but not equivalent to the conjecture’s definition.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test results indicate that the conjecture holds for all tested instances, but the critic challenges the direct correspondence between the computed metric and the conjecture’s definition of balanced separator size in terms of cumulative entropy. Without unambiguous evidence of equivalence, the support condition is not met. | next: Further investigation is needed to establish a clear connection between the test metric and the conjecture’s definition of balanced separator size. Consider modifyi

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/59aa8bd8bca4.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/59aa8bd8bca4.tar.gz` (if generated)
