Φ under a BAD elimination ...

Entry bc8aff5056cd · INCONCLUSIVE

SEC autonomous research engine — attribution: Ludovico Kubler

2026-06-16 07:06:39 UTC

[c003b_cumulative_entropy/SC4#c3] Φ under a BAD elimination order (max-occurrence) exceeds Φ under min-occurrence by a factor growing in n (order-sensitivity of cumulative entropy).

Entry ID: bc8aff5056cd **Verdict:** INCONCLUSIVE **Recorded:** 2026-06-16 07:06:39 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

Φ under a BAD elimination order (max-occurrence) exceeds Φ under min-occurrence by a factor growing in n (order-sensitivity of cumulative entropy).

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(\pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d -regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 624af263b3dff451

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the ratio of Φ under max-occurrence to Φ under min-occurrence grows at least linearly with n , where n is the number of elements, and the ratio exceeds 1.5 for all seeds. The conjecture is falsified if this ratio does not exceed 1.2 for any seed or if it fails to grow linearly with n .

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	UNCERTAIN	1.00	HITS	UNCERTAIN
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
KARP_LIPTON	SAFE	0.50	UNCERTAIN	UNCERTAIN

4. Novelty audit

Verdict: NOVEL against 0 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - resolution proof complexity AND Tseitin formulas AND order sensitivity
- cumulative entropy AND max-occurrence AND resolution proof complexity - Tseitin formulas
AND min-occurrence AND order-sensitivity of cumulative entropy

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=1.1s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).

Computes the REAL cumulative proof entropy
  Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
  proofStateEntropy(sigma) := sigma.activeClauses.card
  cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old script: it tracks
the active clause database at EVERY elimination step of a genuine resolution
derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):
- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample
  30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per-n wallclock guard so a
  hard instance does not stall the cycle.
- Separate log-log slope fits for phi_count (SC1) and phi_weight (SC3).
- Path-graph control at n=12 (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at n=12 on seed[0] (for SC4
  order-sensitivity), throttled to one bad-order DP per cycle.
Pure stdlib (no networkx/pysat). Protocol: run_trial(seed)->dict with
TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
```

above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code does not provide enough detail on the implementation of the cumulative entropy calculation. The statement mentions ‘order-sensitivity of cumulative entropy,’ but the test code only outputs the number of active clauses and their weights at each step, without explicitly showing how these values contribute to a cumulative entropy factor that grows in n.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code does not provide enough detail on the implementation of the cumulative entropy calculation, and the critic has challenged the interpretation of the results. | next: Further investigation is needed to clarify the relationship between the calculated metrics and the cumulative entropy. Provide a detailed explanation of how the ‘phi_count’ and ‘phi_weight’ values contribute to the cumulative entropy factor.

(full prompt+response transcripts available in research/audit/bc8aff5056cd.jsonl)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/bc8aff5056cd.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/bc8aff5056cd.tar.gz` (if generated)
