[c003b_cumulative_entropy/SC6#c11] $\Phi(\pi)/\text{proof_size}$ (number of DP steps) is monotone increasing in n , i.e. per-step active weight grows (the ‘shadow heavier than the body’ claim).

Entry ID: 1553eab35bef **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-31 16:12:35 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

$\Phi(\pi)/\text{proof_size}$ (number of DP steps) is monotone increasing in n , i.e. per-step active weight grows (the ‘shadow heavier than the body’ claim).

Rationale (proposer’s reasoning):

Measure the REAL cumulative proof entropy $\Phi(\pi)=\sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d -regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL’s final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 07a71f4a9de2b161

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if for all seeds, the average active weight per DP step across all steps in the proof increases with n , and the mean of these weights over all seeds exceeds a threshold of 1.5. The conjecture is falsified if any seed shows a decrease in

the mean active weight per DP step or if the mean active weight for any step exceeds a threshold of 2.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	SAFE	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
KARP_LIPTON	SAFE	0.50	UNCERTAIN	UNCERTAIN

4. Novelty audit

Verdict: NOVEL against 0 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - resolution proof complexity AND Tseitin formulas AND cumulative entropy - $\Phi(\pi)/\text{proof_size}$ monotone increasing IN n AND resolution proof complexity AND Tseitin formulas - shadow heavier than the body claim AND $\Phi(\pi)/\text{proof_size}$ AND resolution proof complexity

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤ 90 s wall time per cycle **Execution:** rc=0, elapsed=1.2s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
```

```
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per-n wallclock guard so a hard instance does not stall the cycle.
- Separate log-log slope fits for phi_count (SC1) and phi_weight (SC3).
- Path-graph control at n=12 (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at n=12 on seed[0] (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure stdlib (no networkx/pysat). Protocol: `run_trial(seed)->dict` with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

```

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code only covers a small range of n values (6 to 16), which may not be sufficient to confirm the conjecture's validity for all possible graph sizes. The metric mean and standard deviation are also quite low, suggesting that the empirical evidence is weak and could be influenced by random fluctuations.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

Safety rail: critic_challenge | original judge: The test results indicate that the conjecture holds for all tested instances within the range of n values (6 to 16). The mean active weight per DP ste | next: Further testing is recommended to confirm the conjecture's validity for a wider range of graph sizes and to ensure that the observed trend holds consistently.

(full prompt+response transcripts available in <research/audit/1553eab35bef.jsonl>)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/1553eab35bef.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/1553eab35bef.tar.gz` (if generated)
