Minimal Rank of Tropical Curves Bounds Cumulative Proof Entropy

Entry ID: b95366fb265e **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-29 11:55:04 UTC

1. Conjecture

Field A (mathematical branch): Tropical Geometry **Field B** (complexity object): Resolution proof complexity

Statement:

For every Tseitin formula π with m clauses and n variables, the cumulative proof entropy $\Phi(\pi)$ over its resolution refutation is bounded by $O(\min(m, n^{(3/2)}))$. Equivalently: $|\Phi(\pi)| \leq c * \min(m, n^{(3/2)})$ for some absolute constant c .

Rationale (proposer's reasoning):

Tropical geometry provides a structured way to encode Boolean functions and their properties. The minimal rank of tropical curves may capture the complexity hidden in Tseitin formulas that is not visible through simple counting arguments like clause counts or variable counts alone. A lower bound on the minimal rank could provide a more nuanced understanding of proof complexity, potentially uncovering new relationships between resolution proofs and other complexity measures.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 1b2b4512b81533b1

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The cumulative proof entropy $\Phi(\pi)$ of a Tseitin formula π with m clauses and n variables is supported if $|\Phi(\pi)| \leq c * \min(m, n^{(3/2)})$ for all seeds, where c is an absolute constant and the inequality holds for at least 28 out of 30 random seeds.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	SAFE	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	0.50	UNCERTAIN	UNCERTAIN
KARP_LIPTON	SAFE	1.00	SAFE	SAFE

4. Novelty audit

Verdict: NOVEL against 0 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - "tropical geometry" AND "resolution proof complexity" AND "cumulative proof entropy" - "minimal rank of tropical curves" AND "proof complexity lower bound" - "Tseitin formula" AND "resolution refutation" AND "entropy bound"

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=0.4s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

```

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test only includes n up to 14 and does not provide evidence for n greater than 15. Since the conjecture involves $O(\min(m, n^{(3/2)}))$, testing with $n \leq 15$ may not be sufficient to confirm the bound for larger values of n .

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

Safety rail: critic_challenge | original judge: The test results show that the conjecture holds for all tested instances up to $n=14$, and the aggregate metric supports the conjecture with a high conf | next: Further testing is needed to confirm the conjecture for values of n greater than 15. It would be beneficial to extend the range of n and ensure that the inequality holds consistently across different seeds.

11. Audit log (LLM calls)

Total LLM calls: 7

#	Phase	Provider	Model	Tokens in	out	Latency (ms)

(full prompt+response transcripts available in `research/audit/b95366fb265e.jsonl`)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/b95366fb265e.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/b95366fb265e.tar.gz` (if generated)
