The width-aware totalLite...

Entry c8ef311614f6 · INCONCLUSIVE

SEC autonomous research engine — attribution: Ludovico Kubler

2026-05-31 18:18:20 UTC

[c003b_cumulative_entropy/SC3#c44] The width-aware total-LiteralWeight $\sum_t \sum_{C \in \sigma_t} |C|$ scales with a strictly larger exponent than the count-based Φ (width amplifies cumulative weight).

Entry ID: c8ef311614f6 **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-31 18:18:20 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

The width-aware totalLiteralWeight $\sum_t \sum_{C \in \sigma_t} |C|$ scales with a strictly larger exponent than the count-based Φ (width amplifies cumulative weight).

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(\pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d-regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n, separator size |S|, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): dfc4c21dc9fd39f5

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if the ratio of the width-aware totalLiteralWeight to the count-based Φ exceeds a strictly larger exponent for at least 80% of the seeds, with an aggregate mean difference exceeding 1.5.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤ 90 s wall time per cycle **Execution:** rc=0, elapsed=1.1s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per-n wallclock guard so a hard instance does not stall the cycle.

- Separate log-log slope fits for `phi_count` (SC1) and `phi_weight` (SC3).
- Path-graph control at `n=12` (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at `n=12` on `seed[0]` (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure `stdlib` (no `networkx/pysat`). Protocol: `run_trial(seed)->dict` with `TRIAL/RESULT` lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code does not provide a clear implementation of the width-aware totalLiteralWeight $\sum_t \sum_{C \in \sigma_t} |C|$, which is crucial for confirming the conjecture. The provided output only shows statistics and trial results but lacks the actual computation details that would allow us to verify the correctness of the metric against the mathematical definition.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code does not provide a clear implementation of the width-aware totalLiteralWeight, which is crucial for confirming the conjecture. The provided output only shows statistics and trial results but lacks the actual computation details. | next: Implement and provide a clear definition of the width-aware totalLiteralWeight to verify the conjecture.

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in research/audit/c8ef311614f6.jsonl for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: research/pvsnp_sandbox/test_*.py (per-cycle)

Replay tarball: research/replay/c8ef311614f6.tar.gz (if generated)
