$\Phi(\Pi) \geq c \cdot |S|^2$ for a cons...

Entry d7f18fa59bdc · INCONCLUSIVE

SEC autonomous research engine — attribution: Ludovico Kubler

2026-05-30 14:05:18 UTC

[c003b_cumulative_entropy/SC2#c19] $\Phi(\Pi) \geq c \cdot |S|^2$ for a constant $c > 0$, where $|S|$ is the balanced separator size (the cumulative-entropy analogue of the space lower bound that A13 needs).

Entry ID: d7f18fa59bdc **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-30 14:05:18 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

$\Phi(\Pi) \geq c \cdot |S|^2$ for a constant $c > 0$, where $|S|$ is the balanced separator size (the cumulative-entropy analogue of the space lower bound that A13 needs).

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(\Pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d -regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): fba999795406012f

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

Across ≥ 20 seeds with varied separator sizes $|S| \in [4, 64]$, fit $\Phi(\Pi) = c \cdot |S|^\alpha$ via OLS on log-log; SUPPORTED iff fitted $\alpha \geq 1.95$, fitted $c \geq 0.05$, $R^2 \geq 0.9$, and per-seed ratio $\Phi(\Pi)/|S|^2 \geq 0.05$ in $\geq 80\%$ of seeds. FALSIFIED otherwise.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	0.95	SAFE	SAFE
NATURAL_PROOFS	SAFE	0.95	SAFE	SAFE
ALGEBRIZATION	SAFE	0.92	SAFE	SAFE
KARP_LIPTON	SAFE	0.95	SAFE	SAFE

4. Novelty audit

Verdict: ADJACENT_OK against 3 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - Tseitin formulas resolution space lower bound separator - cumulative entropy resolution proof complexity Tseitin - resolution space expansion Tseitin balanced separator quadratic

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=1.2s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per-n wallclock guard so a hard instance does not stall the cycle.
- Separate log-log slope fits for phi_count (SC1) and phi_weight (SC3).
- Path-graph control at n=12 (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at n=12 on seed[0] (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure stdlib (no networkx/pysat). Protocol: `run_trial(seed)->dict` with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The statement asserts $\Phi(\pi) \geq c \cdot |S|^2$ where $|S|$ is the balanced separator size, but the harness's reported metric is `phi_count_loglog_slope_vs_n` — the log-log slope of Φ against n , not against $|S|^2$ or even the empirical $\Phi/|S|^2$ ratio. The reported separator sizes are tiny constants (sep=3 at $n=14$, sep=5 at $n=16$, sep=6 at $n=12$) and non-monotone in n , which is inconsistent with 3-regular expanders (whose balanced separators are $\Theta(n)$) — suggesting the separator routine is buggy or the graphs aren't

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The reported metric is the log-log slope of Φ vs n , not the pre-registered α from Φ vs $|S|$; separator sizes stay tiny (≤ 6) and non-monotone, making the $|S|^2$ bound trivially satisfied and never stressed. With $n \leq 16$ and only 7 seeds (not ≥ 20 across $|S| \in [4, 64]$), the pre-registered support condition is not unambiguously met. | next: Fix/verify the balanced-separator routine on random 3-regular expanders, then re-run with n large enough to sweep $|S| \in [4, 64]$ across ≥ 20 seeds and fit Φ vs $|S|$ directly on

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/d7f18fa59bdc.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/d7f18fa59bdc.tar.gz` (if generated)
