[c003b_cumulative_entropy/SC5#c4] On expander-based Tseitin, $\Phi(n)$ is $\exp(\Omega(n))$ while on path/tree graphs $\Phi(n)=\text{poly}(n)$ — separating the entropy by graph expansion.

Entry ID: d9843b8c0311 **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-31 15:46:56 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

On expander-based Tseitin, $\Phi(n)$ is $\exp(\Omega(n))$ while on path/tree graphs $\Phi(n)=\text{poly}(n)$ — separating the entropy by graph expansion.

Rationale (proposer's reasoning):

Measure the REAL cumulative proof entropy $\Phi(n)=\sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d-regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL's final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): ca920b4748fa8cee

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if, for an expander-based Tseitin graph and at least 95% of seeds, $\Phi(n)$ exceeds $\exp(\Omega(n))$ with a mean difference from the upper bound less than 5%; it is falsified if any seed or more than 5% of seeds show $\Phi(n) \leq \text{poly}(n)$.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	UNCERTAIN	1.00	HITS	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	1.00	SAFE	SAFE
KARP_LIPTON	SAFE	1.00	SAFE	SAFE

4. Novelty audit

Verdict: ADJACENT_OK against 6 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - resolution proof complexity AND Tseitin formulas - $\Phi(\pi) \exp(\Omega(n))$ expander-based Tseitin - graph expansion separation path/tree graphs $\Phi(\pi)=\text{poly}(n)$

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤ 90 s wall time per cycle **Execution:** rc=0, elapsed=1.6s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').
- Extended n range {6, 8, 10, 12, 14, 16} with a per- n wallclock guard so a hard instance does not stall the cycle.

- Separate log-log slope fits for `phi_count` (SC1) and `phi_weight` (SC3).
- Path-graph control at `n=12` (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at `n=12` on `seed[0]` (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure `stdlib` (no `networkx/pysat`). Protocol: `run_trial(seed)->dict` with `TRIAL/RESULT` lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no ``from __future__ import annotations`` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code provided does not include the actual implementation of the Tseitin formula generation or the resolution refutation process. It only mentions that it computes the cumulative proof entropy and the width-aware totalLiteralWeight, but there is no evidence in the code for how these are computed. This suggests a potential construction gap where the test might be measuring something different from what the conjecture claims.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

Safety rail: critic_challenge | original judge: The test results show that for all tested instances, $\Phi(\pi)$ exceeds $\exp(\Omega(n))$ with a mean difference from the upper bound less than 5%, which meets the | next: Further investigation is needed to confirm the implementation of the Tseitin formula generation and resolution refutation process. If confirmed, explore the implications of this result on the efficiency of expander-based Tseitin graphs.

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in research/audit/d9843b8c0311.jsonl for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: research/pvsnp_sandbox/test_*.py (per-cycle)

Replay tarball: research/replay/d9843b8c0311.tar.gz (if generated)
