Minimal Order of p-Adic Differentials Bounds Cumulative Proof Entropy

Entry ID: f950012983f7 **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-30 05:18:00 UTC

1. Conjecture

Field A (mathematical branch): Algebra (p-adic Numbers) **Field B** (complexity object): Cumulative space (Proof entropy)

Statement:

For a given Tseitin formula φ with n variables, the cumulative proof entropy $\Phi(\varphi)$ is upper-bounded by $O(\log^2(n))$ when φ is transformed into an equivalent system of p-adic differential equations over the p-adic integers. Specifically, if φ has a resolution refutation with width w and depth d , then $\Phi(\varphi) = \Theta(\log^2(wd))$.

Rationale (proposer's reasoning):

p-adic differential equations provide a precise algebraic structure that captures the complexity of the proof process in resolution. The minimal order of these differentials can be computed efficiently for small instances, which allows us to estimate the proof entropy. This connection could reveal a new avenue for understanding the intrinsic complexity of SAT problems.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): f6e687f495b1b91a

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture states that cumulative proof entropy $\Phi(\varphi)$ of a Tseitin formula φ is upper-bounded by $O(\log^2(n))$. The acceptance criterion is to confirm this by showing that for all random seeds, the maximum cumulative proof entropy across all formulas with n variables does not exceed $4 * \log^2(n)$, where $\log$ is base 2.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	UNCERTAIN	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	1.00	SAFE	SAFE
KARP_LIPTON	SAFE	1.00	SAFE	UNCERTAIN

4. Novelty audit

Verdict: ADJACENT_OK against 3 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - "p-adic differential equations" AND "proof entropy" - "Tseitin formula" AND "cumulative proof entropy" AND p-adic - "resolution refutation" width d depth AND cumulative proof entropy"

Top relevant hits considered: - [http://arxiv.org/abs/2305.01463v2] Test of lepton flavour universality using $B^0 \rightarrow D^{*-}\tau^+\nu_\tau$ decays with hadronic τ channels - [http://arxiv.org/abs/2604.05701v1] Measurement of the CKM angle γ in $B^\pm \rightarrow D(\rightarrow K_S^0 h'^+ h'^-) h^\pm$ dec - [http://arxiv.org/abs/1911.05957v2] Determination of quantum numbers for several excited charmed mesons observed in $B^- \rightarrow D^{*+}\pi^-\pi^-$ decays

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤ 90 s wall time per cycle **Execution:** rc=0, elapsed=0.5s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

```

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test only considers up to $n = 14$ for the metric mean calculation, which is too small to establish a strong empirical basis for the conjecture. The metric may not scale trivially with n , and the results could be an artifact of this limited range.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test only considers up to $n = 14$, which may be too small to establish a strong empirical basis for the conjecture. The critic challenged the results due to the limited range of n values. | next: Increase the range of n values tested and re-evaluate the conjecture's validity.

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in `research/audit/f950012983f7.jsonl` for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: `research/pvsnp_sandbox/test_*.py` (per-cycle)

Replay tarball: `research/replay/f950012983f7.tar.gz` (if generated)
