Block-Composition Sub-Additivity of Coarse Depth κ via the Roe-Trace Pairing

- **Verdict:** INCONCLUSIVE
- **Bridge:** Coarse Geometric Karchmer-Wigderson (CG-KW); Roe-style coarse cohomology / coarse geometry of metric spaces (geometric group theory + index theory branch of analysis) $\times$ Boolean formula depth lower bounds for KRW-style block compositions $f \circ g$, the central complexity-theoretic object behind $P \not\subseteq NC^1$; equivalently the depth complexity $D(f \circ g)$ of the composed function in the Karchmer-Raz-Wigderson program
- **Recorded:** 2026-04-28 01:39 UTC
- **Entry ID:** 8047f7f8eea1

Statement

For all boolean functions $f: \{0,1\}^n \rightarrow \{0,1\}$ and $g: \{0,1\}^m \rightarrow \{0,1\}$ for which $HX^1(X_f)$ and $HX^1(X_g)$ admit nontrivial classes detected by Roe-controlled operators, the coarse depth κ defined via the trace pairing on the KW-metric spaces obeys the sub-additive bound $\kappa(f \circ g) \geq \kappa(f) + \kappa(g) - C$, where C is a universal constant independent of n, m , and where $(X_{\{f \circ g\}}, d_{\{f \circ g\}})$ is built by the coarse product operation. In particular, witness cocycles $c_f \boxtimes c_g \in HX^1(X_{\{f \circ g\}})$ and tensor Roe operators $T_f \otimes T_g \in C_u^*[X_{\{f \circ g\}}]$ realize $\log|(c_f \boxtimes c_g, T_f \otimes T_g)| / \log(\text{propagation}(T_f \otimes T_g)) \geq \kappa(f) + \kappa(g) - C$.

Rationale

This sub-conjecture lifts axiom A2 (Composition sub-additivity for asdim) from the asymptotic-dimension layer to the strictly stronger κ layer, and chains through A1 ($\kappa \leq \text{depth}$) to recover the KRW conjecture $D(f \circ g) \geq D(f) + D(g) - O(1)$. The mechanism is the multiplicativity of the Roe-index trace pairing on tensor products: $\langle c_f \boxtimes c_g, T_f \otimes T_g \rangle = \langle c_f, T_f \rangle \cdot \langle c_g, T_g \rangle$ (Connes-style product), while the propagation of $T_f \otimes T_g$ equals $\text{propagation}(T_f) \cdot \text{propagation}(T_g)$ under the depth-additive metric of coarse product. Taking logs yields the additive bound. Should this hold even on small toy compositions, it provides direct empirical support for the KRW direct-sum theorem at the κ level. It does not contradict A3 (anti-natural-proofs) because random f has $\kappa = O(1)$, so additivity holds trivially. It is consistent with A4 (anti-relativization) since coarse product does not introduce oracle gates. A5 (Roe-index rigidity) underpins the stability of the tensor pairing under coarse equivalence.

    ~~~~~
```

TypeError: 'int' object is not iterable

Judge reasoning

The test crashed with a `TypeError` ('int' object is not iterable) at `build_X_d` before any κ values were computed, so no data exists to evaluate the pre-registered support criterion. | next: Fix `build_X_d` to enumerate vertices correctly (e.g., `X = [tuple(b) for b in itertools.product([0,1], repeat=n)]`) and rerun the 25-pair $\times$ 5-seed protocol.

Coboundary-Vanishing Threshold: HX^1 Triviality Below the Diameter-to-Depth Ratio for Parity-on-a-Tree

- **Verdict:** INCONCLUSIVE
- **Bridge:** Coarse Geometric Karchmer-Wigderson (CG-KW) framework / coarse (Roe) cohomology and geometric group theory applied to circuit complexity $\times$ Formula depth lower bounds for the recursive-parity (balanced AND/OR-tree of XORs) function in the NC^1 vs. $AC^0[\oplus]$ regime, expressed via the coarse 1-cohomology $HX^1(X_f)$ and the Roe-trace pairing on $C_u^*[X_f]$
- **Recorded:** 2026-04-28 03:39 UTC
- **Entry ID:** 264c40c0d040

Statement

Let $f_n = \oplus\text{-tree}_n$ be the balanced binary tree of XOR gates on $n = 2^k$ inputs, with KW-metric space $(X_{\{f_n\}}, d_{\{f_n\}})$. Define the coboundary $\delta : C^0_{\text{coarse}}(X_{\{f_n\}}) \rightarrow C^1_{\text{coarse}}(X_{\{f_n\}})$ and the propagation-R Roe subalgebra $C_u^*[X_{\{f_n\}}]_R$. Then there exists a universal constant $\alpha \in (0,1)$ such that, for all $R \leq \alpha \log_2 n$, every coarse 1-cocycle c with propagation $\leq R$ is a coboundary (so its class in HX^1 is trivial), while for $R \geq k = \log_2 n$ there exist nontrivial classes c whose Roe-trace pairing satisfies $\log|c, T| / \log(\text{propagation}(T)) \geq k - O(1)$. Consequently $\kappa(f_n) \geq \log_2 n - O(1)$, matching $\text{depth}(f_n) = \Theta(\log n)$ up to constants and certifying axiom A1 sharply for an explicit recursive function.

Rationale

This conjecture directly tests axiom A1 (Coarse-KW link) together with A5 (Roe-index rigidity) on the canonical recursive function whose formula depth is exactly known ($\text{depth}(\oplus\text{-tree}_n) = \log_2 n$).

The KW protocol for the parity tree must descend the tree to find a differing leaf, so the controlled-cover multiplicity must grow by 1 per level; this should manifest as a vanishing-threshold for HX^1 at propagation $R \approx \log_2 n$, with cocycles at smaller propagation forced to be coboundaries. Verifying both the vanishing below the threshold and the nonvanishing above gives a sharp quantitative version of A1 on a function whose depth we can independently certify, providing a sanity check that k is neither overshooting nor undershooting the true formula depth in a controlled recursive setting.

           ~~~~^
```

IndexError: list index out of range

Judge reasoning

The test crashed with an IndexError in the xor_tree construction before any data on $R^*(n)$, $\dim HX^1_R$, or slope correlations was produced, so neither the support nor falsification conditions can be evaluated. | next: Fix the xor_tree recursion (the base case and/or input length handling causing the out-of-range index) and rerun the pre-registered protocol across $n \in \{4, 8, 16, 32\}$.

Multiplicity-Doubling Lower Bound from Protocol Pullback on Indexing Gadgets

- **Verdict:** INCONCLUSIVE
- **Bridge:** Coarse Geometric Lifting (CGL) / Coarse Geometry & Roe-Algebra methods in Communication Complexity $\times$ Deterministic two-party communication complexity $CC(f \circ G^n)$ of lifted boolean functions
- **Recorded:** 2026-04-28 08:37 UTC
- **Entry ID:** 6a6a970e1f5b

Statement

Let $G = \text{IND}_b$ be the standard indexing MetricGadget on $X = \{0,1\}^b \times [b]$, $Y = [b]$ with d the Hamming metric on $X \times Y$, and let $f: \{0,1\}^n \rightarrow \{0,1\}$ have deterministic decision-tree complexity $Q(f)$. Then for the lifted input space $((X \times Y)^n, d_{\oplus})$ at scale $R = \text{diam}(G)$, every deterministic protocol Π computing $f \circ G^n$ satisfies $\text{CoarsePullbackProtocol}(\Pi) = (m_{\Pi}, R_{\Pi})$ with $m_{\Pi} \geq 2^{\{Q(f)\} / \text{poly}(b, n)}$, so by axiom A2, $\text{CC}(f \circ G^n) \geq Q(f) - O(\log(bn))$. Equivalently, $\text{CLC}(f, \text{IND}_b) \geq Q(f) \cdot \log_2(\text{asdim}_R(\text{IND}_b^{\{\otimes n\}}) + 1) - O(\log(bn))$, recovering the Raz-McKenzie bound through the coarse-cover route.

Rationale

This sub-conjecture directly tests axiom A2 (Protocol $\rightarrow$ Cover) on the canonical gadget for which Raz-McKenzie lifting is known to hold, using axiom A3 (Asdim Amplification) to guarantee that the iterated indexing gadget has unbounded coarse dimension proportional to n . If A2 is sound, the multiplicity of the protocol-induced RoeCover must scale exponentially in the query complexity, otherwise one could collapse a query-tree lower bound through a low-multiplicity cover — contradicting the structure theorem at the heart of CGL. Confirming the bound on small parameters provides empirical evidence that the coarse-cover viewpoint reproduces the standard query-to-communication lift, a necessary sanity check before pursuing axiom A4's non-relativizing strengthening.

EOFError: EOF when reading a line

Judge reasoning

The test crashed with an EOFError while reading seeds from stdin before any data could be produced, so neither the support nor falsification conditions can be evaluated. | next: Patch the harness to provide default seeds (or read from argv/env) when stdin is empty, then rerun the ≥ 20 -trial battery over $b \in \{2,3,4\}$, $n \in \{2,3,4\}$.

Σ^b_0 -PIND Width-2 Closure Round-Count vs DPLL Leaves

- **Verdict:** INCONCLUSIVE
- **Bridge:** Bounded arithmetic / Cook-Reckhow-Krajicek correspondence: the Σ^b_0 -PIND round count $r_2(F)$, defined as the minimum $k \in \mathbb{N} \cup \{\infty\}$ such that iterating the closure operator $\Phi(S) = S \cup \{C : |C| \leq 2 \text{ and } C \text{ is RUP-derivable from } F \cup S \text{ in one unit-propagation pass}\}$ k times yields $\perp \in \Phi^k(\square)$; r_2 captures the depth of sharply-bounded polynomial-time

induction in PV restricted to width-2 reasoning (Cook-Reckhow lineage; rarely measured directly as a quantitative invariant on small unsatisfiable CNFs). × Lex-DPLL search-tree leaf count $L(F)$ on small unsatisfiable 3-CNF formulas under a fixed lexicographic variable order with unit propagation, equivalently tree-resolution leaf count up to constants.

- **Recorded:** 2026-04-28 08:46 UTC
- **Entry ID:** fc9124ecdaa8

Statement

For every unsatisfiable 3-CNF F on $n \leq 14$ variables and $m \leq 6n$ clauses: (a) if $r_2(F) < \infty$, then $\log_2 L(F) \leq 2 \cdot r_2(F) + 2 \cdot \log_2(n+1)$; (b) if $r_2(F) = \infty$, then $\log_2 L(F) \geq n/4$. Equivalently, finiteness of width-2 RUP closure forces a polynomial DPLL bound, while non-closure forces an exponential one — a sharp dichotomy.

Rationale

Width-2 RUP closure is the propositional shadow of Cook's PV restricted to the sharply-bounded Σ^b_0 -PIND fragment, the weakest layer of the Buss hierarchy. The Cook-Reckhow-Krajicek correspondence predicts a polynomial relation between sharply-bounded PV-proof depth and tree-like resolution size; quantifying it should expose the exact slack and yield a dichotomy mirroring the classical PHP/Tseitin obstructions to weak proof systems.
