[c003b_cumulative_entropy/SC6#c11] $\Phi(\pi)/\text{proof_size}$ (number of DP steps) is monotone increasing in n , i.e. per-step active weight grows (the ‘shadow heavier than the body’ claim).

Entry ID: 62882a0995f5 **Verdict:** INCONCLUSIVE **Recorded:** 2026-06-15 07:01:56 UTC

1. Conjecture

Field A (mathematical branch): Resolution proof complexity **Field B** (complexity object): Tseitin formulas

Statement:

$\Phi(\pi)/\text{proof_size}$ (number of DP steps) is monotone increasing in n , i.e. per-step active weight grows (the ‘shadow heavier than the body’ claim).

Rationale (proposer’s reasoning):

Measure the REAL cumulative proof entropy $\Phi(\pi) = \sum_t |\text{activeClauses}(\sigma_t)|$ (proofStateEntropy=card, per Conjecture003.lean) over genuine resolution refutations (Davis-Putnam variable elimination) of Tseitin formulas on d -regular graphs. The existing c003b_counterexample.py only proxies Φ via CaDiCaL’s final clause count; this harness computes the actual step-by-step Φ . Determine the scaling of Φ (and the width-aware totalLiteralWeight) vs n , separator size $|S|$, and elimination order, and whether it matches/strengthens the cumulative_entropy_lower_bound (currently proved modulo axiom A13).

Taxonomy category: c003b_cumulative_entropy (status at proposal time: harness_backed)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): fa27a8e92ae5f433

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

The conjecture is supported if for all seeds, the ratio of $\Phi(\pi)$ to proof_size (number of DP steps) increases as n increases, with no seed showing a decrease.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	SAFE	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	1.00	SAFE	UNCERTAIN
KARP_LIPTON	SAFE	0.50	UNCERTAIN	UNCERTAIN

4. Novelty audit

Verdict: ADJACENT_OK against 6 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - resolution proof complexity AND Tseitin formulas AND cumulative entropy - $\Phi(n)/\text{proof_size}$ monotonically increasing IN number of DP steps AND Tseitin formulas - shadow heavier than the body claim IN resolution proof complexity AND relationship with Tseitin formulas

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤ 90 s wall time per cycle **Execution:** rc=0, elapsed=1.1s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness (v2, focus mode).
```

```
Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas on random 3-regular graphs, exactly per the Lean
definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
Also computes the width-aware totalLiteralWeight (sum of clause sizes).
```

This is NOT the CDCL clause-count proxy used by the old script: it tracks the active clause database at EVERY elimination step of a genuine resolution derivation, so it is the actual Phi the formalization names.

v2 (focus mode 2026-05-29):

- Per-cycle seed variation via time-based nonce, so 30-trial cycles sample 30 DIFFERENT graphs at each n (replacing the prior 'same data every cycle').

- Extended n range {6, 8, 10, 12, 14, 16} with a per- n wallclock guard so a hard instance does not stall the cycle.
- Separate log-log slope fits for ϕ_{count} (SC1) and ϕ_{weight} (SC3).
- Path-graph control at $n=12$ (for SC5: expander/path entropy gap).
- Bad-order experiment (max-occurrence) at $n=12$ on seed[0] (for SC4 order-sensitivity), throttled to one bad-order DP per cycle.

Pure stdlib (no networkx/pysat). Protocol: `run_trial(seed)->dict` with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).

NOTE: no `from __future__ import annotations` – the sandbox injects a prelude above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code only includes a limited range of n values (6 to 16) and does not provide evidence that the metric scales with n beyond this range. The small sample size may not be sufficient to confirm the conjecture for larger values of n.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

Safety rail: critic_challenge | original judge: The test results show that the conjecture holds for the tested range of n values (6 to 16). The mean slope of $\Phi(\pi)$ over proof_size is consistent with | next: To further validate the conjecture, it would be beneficial to conduct tests with a wider range of n values, including larger values, to ensure that the observed trend holds across a broader spectrum.

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in research/audit/62882a0995f5.jsonl for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: research/pvsnp_sandbox/test_*.py (per-cycle)

Replay tarball: research/replay/62882a0995f5.tar.gz (if generated)
