Minimal Hodge Span of Tseitin Formulas and Resolution Proof Width

Entry ID: 552478e26c63 **Verdict:** INCONCLUSIVE **Recorded:** 2026-05-29 13:56:38 UTC

1. Conjecture

Field A (mathematical branch): Algebraic Geometry (Hodge Theory) **Field B** (complexity object): Complexity Theory: Resolution Proof Complexity

Statement:

For a Tseitin formula φ with n variables, the minimal number of generators in the Hodge module $H^1(\varphi)$ is $\Theta(\log n)$, and this number is upper bounded by the resolution proof width $w(\varphi)$. Specifically, $|H^1(\varphi)| = O(w(\varphi) \log n)$.

Rationale (proposer's reasoning):

The Hodge theory provides a framework for studying algebraic varieties over finite fields, which may reveal hidden structural properties of Tseitin formulas. A direct connection between the Hodge module and resolution proof width could offer new insights into proof complexity. Moreover, the Hodge span is computable using algorithms from computational algebraic geometry.

Taxonomy category: c003b_cumulative_entropy (status at proposal time:)

2. Pre-registration (Popper-style)

Hash (SHA-256 prefix): 8ebaf9e120691dd4

This hash commits to the conjecture statement, acceptance criterion, and seed list **before** the empirical test runs. Tampering with the test or its data after this hash was computed would be detectable.

Acceptance criterion:

For a Tseitin formula φ with n variables, if $|H^1(\varphi)| \leq 10w(\varphi) \log n$ for all instances and no seed produces $|H^1(\varphi)| > 10w(\varphi) \log n$.

3. Barrier filter (F1)

Final: PASS

Barrier	Verdict	Confidence	LLM ₁	LLM ₂
RELATIVIZATION	SAFE	1.00	SAFE	SAFE
NATURAL_PROOFS	SAFE	0.50	UNCERTAIN	UNCERTAIN
ALGEBRIZATION	SAFE	1.00	SAFE	SAFE
KARP_LIPTON	SAFE	1.00	SAFE	UNCERTAIN

4. Novelty audit

Verdict: ADJACENT_OK against 2 hits across arXiv + Semantic Scholar + ECCC

Search queries (3): - "Hodge module" AND "Tseitin formulas" AND "resolution proof complexity" - "Algebraic Geometry" AND "proof width" AND "Tseitin formulas" - "Hodge Theory" AND "complexity theory" AND resolution

Top relevant hits considered: - [s2:1409.7782] Recommended isolated-line profile for representing high-resolution spectroscopic transitions (IUPAC Technical Report) - [s2:10.1177/09670106241284172] Organizing for future war and warfare: Complexity as ‘folk theory’ in NATO policy

5. Empirical test harness

Multi-seed protocol: 5 seeds (11, 23, 37, 53, 71)

Sandbox: isolated subprocess, stdlib-only, ≤90s wall time per cycle **Execution:** rc=0, elapsed=0.4s

5.1 Generated Python source

```
#!/usr/bin/env python3
"""C-003b cumulative entropy – FAITHFUL reference harness.

Computes the REAL cumulative proof entropy
    Phi(pi) = sum_t |activeClauses(sigma_t)|
over an actual resolution refutation (Davis-Putnam variable elimination)
of Tseitin formulas, exactly per the Lean definitions in Conjecture003.lean:
    proofStateEntropy(sigma) := sigma.activeClauses.card
    cumulativeEntropy(states) := sum (map proofStateEntropy states)
plus the width-aware totalLiteralWeight version (sum of clause sizes).

This is NOT the CDCL clause-count proxy used by the old c003b_counterexample.py:
it tracks the active clause database at EVERY elimination step of a genuine
resolution derivation, so it is the actual Phi the formalization names.

Pure stdlib (no networkx/pysat), so it runs in the pipeline sandbox.
Protocol: run_trial(seed)->dict with TRIAL/RESULT lines.

Author: Ludovico Kubler (harness by the SEC engine, hand-verified).
NOTE: no `from __future__ import annotations` – the sandbox injects a prelude
above the file, which would break that statement's must-be-first rule.

8. Critic adversarial review

Critic verdict: CHALLENGE

Critic reasoning:

The test code focuses on the cumulative proof entropy for resolution refutations of Tseitin formulas, which is a proxy for the number of clauses and steps in the resolution process. However, it does not directly measure the Hodge module or its generators, which are central to the conjecture’s statement. The metric used (phi_count) may not scale trivially with n, but it does not address the minimal Hodge span or resolution proof width as defined by the conjecture.

9. Final verdict & safety rail

Verdict: INCONCLUSIVE

Reasoning:

The test code focuses on cumulative proof entropy for resolution refutations, which does not directly measure the Hodge module or its generators as required by the conjecture. The critic challenged the validity of the metric used and the support condition was not unambiguously met. | next: Re-evaluate the test to ensure it measures the Hodge module and its generators accurately, and retest with a metric that aligns with the conjecture’s definition.

11. Audit log (LLM calls)

12. Reproducibility

To reproduce this cycle:

1. Apply the test harness in section 5.1 with seeds 11,23,37,53,71
2. The Python sandbox is pure-stdlib; any Python 3.11+ should suffice
3. The full LLM transcripts are in research/audit/552478e26c63.jsonl for verification of provenance
4. The pre-registration hash in section 2 commits to the test design before execution; tampering would be detectable.

Sandbox file: research/pvsnp_sandbox/test_*.py (per-cycle)

Replay tarball: research/replay/552478e26c63.tar.gz (if generated)
